

Long Chain Hydroxacyl-CoA Dehydrogenase Deficiency (LCHAD)

A fatty acid oxidation disorder

What is it?

Long Chain Hydroxyacyl-CoA Dehydrogenase Deficiency (also known as LCHAD) is an inherited fatty acid oxidation disorder. Patients with fatty acid oxidation disorders, like LCHAD, cannot breakdown fats to energy. Once the body uses up its primary source of energy (glucose, or blood sugar), the body begins to fail because it cannot then make energy from fats. Therefore, people with LCHAD must eat on a very regular basis and should not go long without food.

What are the symptoms?

A person with LCHAD can appear normal at birth. Symptoms are variable and range from recurrent episodes of hypoglycemia and muscle weakness, to heart, liver, or eye problems. These symptoms can progress very quickly to coma, cardiac arrest, brain damage, or even death in children who are not eating well. In addition, mothers of babies with LCHAD can have problems such as HELLP syndrome or acute fatty liver of pregnancy. Many symptoms of LCHAD can be prevented by immediate treatment and lifelong management. People with LCHAD typically receive follow-up care by a team of professionals that is experienced in treating people with metabolic disorders.

Inheritance and frequency

LCHAD is inherited in an autosomal recessive manner. This means that for a person to be affected with LCHAD, he or she must have inherited two non-working copies of the gene responsible for causing LCHAD. Usually, both parents of a person affected with an autosomal recessive disorder are unaffected because they are carriers. This means that they have one working copy of the gene, and one non-working copy of the gene. When both parents are carriers, there is a 1 in 4 (or 25%) chance that both parents will pass on the non working copies of their gene, causing the baby to have LCHAD.

Typically, there is no family history of LCHAD in an affected person. LCHAD is a rare fatty acid oxidation disorder; the total number of people affected with LCHAD is not known.

How is it detected?

LCHAD can be detected through newborn screening. A recognizable pattern of elevated chemicals alerts the laboratory that a baby may be affected. Confirmation of newborn screening results is required to make a firm diagnosis. This is usually done by a physician that specializes in metabolic conditions, or a primary care physician.

How is it treated?

LCHAD is treated by eating frequently and avoiding fasting, babies may be given a

special formula, and sometimes medication, as recommended by a genetic metabolic medical professional.
